

Special characteristics of METALLIC, TEXTURED and TEXTURED-METALLIC powders

In the application of metallic, textured and textured-metallic powders, differences in the aspect and cloud formation are possible. These phenomena lead to the impression that there is a deviation in the colour.

The higher the metallic effect of the applied colour, the higher is the risk that these phenomena will occur.

This phenomenon is inherent to these powders and the production technique that is used.

When textured and textured-metallic powders are applied, blisters can also form on the polyamide isolation strips. These blisters are a consequence of a too high humidity of the strip in combination with a quicker flow of the powder, which is necessary to achieve the textured effect.

ALURAL cannot be made liable for the above-mentioned phenomena, and all direct or indirect claims will be rejected in their entirety.

The 10-year Guarantee after delivery nevertheless remains applicable, as described in the guarantee certificate (see our website www.alural.be).

All applied colours are always an approximation. In conformity with applicable standards, colour and gloss deviations are possible.
